

Appendix: Result interpretation notes

1. This note explains a non-table result paragraph with repeated indentation and many aligned list markers.
2. The specimen may be affected by sampling, transport, amplification or other process factors and needs to be retested.
3. The result is provided for reference only and should not be transformed into columns because it is narrow.
4. If transfer is considered, follow-up diagnosis and routine examination are recommended after pregnancy.
5. Technical limitations include mosaicism, segmental variation, contamination, low coverage and ambiguous results.
6. Current medical testing level and sample quality may lead to deviation or failure in a small number of cases.
7. Sex chromosome analysis can be less efficient than autosome analysis due to amplification and sequencing errors.
8. In rare cases, transfusion, transplantation or other therapy may affect the result and requires separate reporting.
9. False positive or false negative results may occur even when procedures are performed according to specifications.
10. The final interpretation should be combined with clinical information instead of being read as a structured report.

Additional lettered notes

- a. This note explains a non-table result paragraph with repeated indentation and many aligned list markers.
- b. The specimen may be affected by sampling, transport, amplification or other process factors and needs to be retested.
- c. The result is provided for reference only and should not be transformed into columns because it is narrow.
- d. If transfer is considered, follow-up diagnosis and routine examination are recommended after pregnancy.
